

Brainstorming

Heart Disease Analysis — Idea Dump

Analysis Angles

- Exploratory Data Analysis (EDA): distributions of age, cholesterol, blood pressure, etc.
- Correlation analysis between clinical attributes and heart disease presence
- Comparison of risk factors across age groups and gender
- Outlier detection in cholesterol/blood pressure readings

Possible Features / Deliverables

- Interactive dashboard (Power BI / Tableau / Excel) showing key risk indicators
- Correlation heatmap of all clinical variables
- Risk score calculator based on top predictive features
- Classification model (Logistic Regression / Random Forest) to predict heart disease presence
- Feature importance chart to explain which factors matter most

Data Considerations

- Check dataset for missing values, duplicates, and inconsistent categorical labels
- Handle outliers in continuous variables (cholesterol, resting BP, max heart rate)
- Encode categorical variables (chest pain type, thalassemia, etc.) appropriately

Presentation Ideas

- Use plain-language summary alongside technical charts for non-technical stakeholders
- Highlight top 3-5 risk factors prominently on the first dashboard view
- Include a short demo video walking through the dashboard

Open Questions

- Is the goal purely descriptive (EDA) or also predictive (ML model)?
- What dataset will be used — source, size, and license?
- Who is the final audience: clinicians, students, or general stakeholders?
